Process & Decision Documentation

GBDA 302 | Side Quest 5 | Katelyn Nguyen

Project/Assignment Decisions

For this sidequest, I mainly played around with adding in new sprite sheets to the existing code. Which was surprisingly more of a challenge than I initially thought because the free online sprite sheets didn't have the frames into a single sheet like the ones provided in the code. Therefore, I used an online sprite generator in order to place all the frames into a single sheet, overcoming many of my early struggles. Here's a general outline of more decisions and my overall thought process while completing this side quest:

1. Changed player sprite sheet via AssetLoader.js
    a. Changed file location from playerSpriteSheet to hunterSpriteSheet
        i. Downloaded a free online sprite sheet with frames
        ii. Combined frames into a single sprite sheet via generator – basing it off original fox sprite sheet in assets code
    b. Adjusted values and properties within
        i. frames based on row in sprite sheet (starting at 0)
        ii. frameSize [frameWidth, frameHeight] based on calculated frameWidth and frameHeight of spritesheet
            - In order for frames to be properly loaded and displayed
            - frameWidth = Sprite Sheet width / total # of columns
            - frameHeight = Sprite Sheet height / total # of rows
        iii. frameDelay to slow or speed up how frames are shown / animated

```
function defaultPlayerAnis() {
```

    c. Added scale in buildSprites() function within src/PlayerEntity.js to make more appropriate player size
        i.
        ii.
        iii.

```
    this.sprite = new Sprite(this.startX, this.startY, frameW,
frameH);
    this.sprite.rotationLock = true;
    this.sprite.scale = 0.55;
```

        iv. Changed player offset value so feet does not sink into floor via src/enitites/PlayerEntity.js

```
    this.ANI_OFFSET_Y = Number(this.tuning.player?.aniOffsetY ??
-15);
```

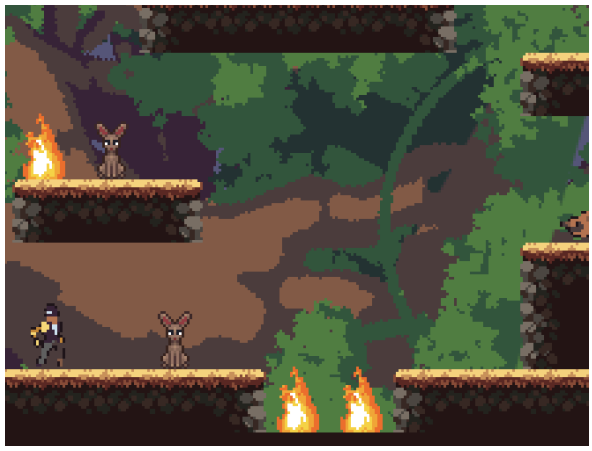
2. Changed leaf sprite sheet via AssetLoader.js
    a. Realizing Leaf.js does not reflect any changes made to it, the changes are shown in the src/world/TileBuilder.js

b. Adjusting offset to remove hare floating

```
level.leaf.anis.offset.y = 0;
```

3. Changing the enemy sprite sheet
    a. Original hyena running in opposite direction -> flipped sprite sheet to reverse movement direction
    b. Challenge: finding the right location to adjust the scaling of hyena, i tried many options and it just wouldn't reflect the sizing adjustment..
4. Adding in new background (unable to add parallax effect)

(before) (after)



Side Quest 6

Name: Katelyn Nguyen

Role(s): Code modifier / Designer

Primary responsibility for this work: Adjust elements such as the background, finding new spritesheets to update entities → player, leaf, and enemy. Adding in audio.

Goal of Work Session

- Add in new sprite sheets for the following entities: player, leaf, enemy
- Change background with different tileset
- Adjust world appearance
- Make sure world behaved appropriately and consistently with correct player movement

Tools, Resources, or Inputs Used

- Example 5 from Week 6 code examples
- Microsoft Copilot
- Week 6 Coding Workshop - Video

GenAI Documentation

Date Used: March 15, 2026

Tool Disclosure: Microsoft Copilot

Purpose of Use: Debugging issues, clarifying code behaviour, brainstorming solutions for any errors, and understanding sprite sheets and frames better.

Summary of Interaction: The tool helped translate my ideas into code, implement features, deal with issues, and compare different approaches.

Human Decision Point(s): I rejected any approaches that seemed overly complex or seemed to add more confusion. I relied on my judgement and the coding workshop to decide what code to include or advice to use or deny.

Integrity & Verification Note: I primarily tested each change in Live Server, checking if any line of code added helped or conflicted. I also periodically checked that GitHub Pages updates were working properly.

Scope of GenAI Use: Any generated code I made sure to review, making changes manually (most notably updated values) and adapted suggestions to fit my project.

Limitations or Misfires: Sometimes the tool suggested more complex approaches than I needed, so I simplified them to match my direction and the assignment scope.

Summary of Process (Human + Tool)

- Broke down the side quest into step-by-step pieces
- Clarified questions and confusions points
- Offered approaches to fix errors and implement changes
- Properly reviewed that changes were being reflected

Decision Points & Trade-offs

Describe one or two key decisions you made:

- Used the free online sprite sheet generator to compile frames into a single file for my player and enemy entities
- Modified existing code to change appearance/background of world

Verification & Judgement

- Playtesting to ensure interactiveness between player and other entities through Live Server
    - Confirming the player can properly interact with entities: “rescue” the hares and experience damage when they run into a fire or hyena
- Reviewing side quest prompt/instructions and Week 6 Coding Workshop video

Limitations, Dead Ends, or Open Questions

- At times GitHub Pages didn’t update, which made me think it was a coding issue when it was actually a caching issue
- Briefly explored more advanced message systems but realized they weren’t necessary for the assignment
- Issues with sound and audio, likely future reattempt to make it functional
